

- c) Discuss the benefits and potential problems of the network configuration used in the previous step.

**Problem 3.2: longest-prefix match forwarding**

(2+2 = 4 points)

IP packets are forwarded by performing a longest-prefix match on the network prefixes. Forwarding tables can be represented as binary or multibit tries. Furthermore, network prefixes can sometimes be aggregated.

In this problem, prefixes are represented using a binary notation (for example, the binary notation “10101000\*” matches all addresses starting with the binary prefix “10101000” which is equivalent to the prefix 168.0.0.0/8 in dotted quad notation). Consider the following three forwarding tables  $F_1$ ,  $F_2$ , and  $F_3$ .

$F_1$	prefix	next hop	$F_2$	prefix	next hop	$F_3$	prefix	next hop
	*	$R_1$		*	$R_2$		*	$R_1$
	00*	$R_2$		01*	$R_1$		1*	$R_3$
	10*	$R_2$		11*	$R_3$		10*	$R_2$
	11*	$R_3$					110*	$R_2$

Assume that the minimum legal network prefix is 8 bit long.

- Are the forwarding tables  $F_1$  and  $F_2$  equivalent? Why or why not?
- Is there an equivalent forwarding table for  $F_3$  with less than four entries? Why or why not?
